## Chapter 2.0

### Concentrations of Sulfur and Nitrogen Species

---

Air pollutant concentrations sampled in 1998 using the CASTNet filter packs are presented and analyzed in this chapter. These concentrations include  $\text{SO}_2$ ,  $\text{SO}_4^{2-}$ ,  $\text{HNO}_3$ ,  $\text{NH}_4^+$ ,  $\text{NO}_3^-$ , and total  $\text{NO}_3^-$  ( $\text{HNO}_3$  plus  $\text{NO}_3^-$  aerosol). In addition, annual and quarterly averages measured at a subset of 34 monitoring sites with the most complete historical record from 1989 through 1998 are presented and analyzed for trends using linear regressions and box plots. The selection of the 34 sites is discussed later in the subsection on 10-year trends.

Quarterly average concentrations were constructed from measured weekly filter concentrations. Quarterly averages were calculated for all sites with at least eight valid weekly values. Annual averages were calculated for all sites with at least three valid quarterly averages.

#### Concentrations

##### *Sulfur Dioxide*

Figure 2-1 presents 1998 annual  $\text{SO}_2$  concentrations. Quarterly averages are provided in Appendix A. Higher concentrations in the

East were observed during the first quarter. The highest concentrations were measured in proximity to the Ohio River from southern Illinois into Pennsylvania with sharp concentration gradients along the peripheries of the network. The highest  $\text{SO}_2$  level in the West was measured at Chiricahua, AZ (CHA467).

##### *Particulate Sulfate*

Annual average  $\text{SO}_4^{2-}$  concentrations for 1998 are presented in Figure 2-2. Quarterly averages are given in Appendix A. Higher values were measured in the East during the third quarter with a band of concentrations above  $10.0 \mu\text{g}/\text{m}^3$  from eastern Kentucky into western Virginia. Concentrations were generally higher in 1998 than in 1997 (see Figure 2-10). The annual  $\text{SO}_4^{2-}$  levels measured throughout the West were generally below  $1.5 \mu\text{g}/\text{m}^3$ . During the third quarter, values at several sites exceeded  $1.0 \mu\text{g}/\text{m}^3$ .

##### *Nitric Acid*

Annual  $\text{HNO}_3$  concentrations are shown in Figure 2-3. Quarterly concentrations are given in Appendix A. The eastern data show local geographic variability and sharp gradients along the peripheries of

the network. Values are higher in the third quarter. Concentrations throughout the west are generally lower, except for southern California where  $\text{HNO}_3$  equals eastern values.

### *Particulate Ammonium*

Figure 2-4 presents annual averages of  $\text{NH}_4^+$  for 1998. Appendix A provides quarterly averages. Eastern concentrations are fairly uniform in the center of the network with gradients along the network peripheries. In general, higher concentrations were measured in agricultural areas, rather than forested areas. Measured  $\text{NH}_4^+$  is generally low throughout the West.

### *Particulate Nitrate*

Annual concentrations of  $\text{NO}_3^-$  aerosols are shown in Figure 2-5. Quarterly average concentrations are given in Appendix A.  $\text{NO}_3^-$  concentrations are more variable geographically than  $\text{SO}_4^{2-}$ , with the highest levels measured in agricultural areas in the Midwest (e.g., Illinois and Indiana). Western concentrations are less than  $1.0 \mu\text{g}/\text{m}^3$ , except for California.

### *Total Nitrate*

Average annual concentrations of total  $\text{NO}_3^-$  are depicted in Figure 2-6. Appendix A provides quarterly averages. The concentrations show considerable local geographic variability in the East. The higher values were observed in the Midwest. The pattern of concentrations in the West is similar to  $\text{HNO}_3$  with relatively high values over California.

### *Ten-Year Trends*

One of the goals of CASTNet is to assess trends in measured concentrations. Trends analyses have been performed using linear regressions of pollutant concentrations averaged over 34 eastern sites versus year from 1989 through 1998.  $\text{SO}_2$  and  $\text{NO}_x$  emissions for eastern states are also shown on the trends diagrams— $\text{SO}_2$  for trends in sulfur species and  $\text{NO}_x$  for trends in nitrogen species. Box plots of annual averages over the 10-year period have also been prepared. The 34 sites (Figure 2-7) were selected using criteria similar to those used by EPA (1998) in their annual trends report. Sites with complete data for 8 of the 10 years were selected. Missing quarterly data were interpolated from adjacent quarterly data, e.g., first quarter 1996 data were interpolated from 1995 and 1997 first quarter data. Missing quarterly averages for 1989 or 1998 were assumed equal to adjacent quarterly values. A valid quarterly average was based on eight valid weeks. Annual averages were based on data from four quarters. No trends analyses were performed for western sites based on previous calculations (e.g., CASTNet Deposition Summary Report).

Figure 2-8 shows linear regressions based on annual and quarterly average  $\text{SO}_2$  concentrations for the 34-station subset. Annual  $\text{SO}_2$  emissions for states east of and including the north-south line of states from Minnesota to Louisiana are also depicted. The figure shows

significant reductions in annual and quarterly  $\text{SO}_2$  averages. The linear model indicates about a 46% reduction in annual  $\text{SO}_2$  levels. The slope of the regression line is smaller than those shown in previous analyses (e.g., 0.68 in the 1997 Annual Report and 0.73 in the Deposition Summary Report). The reduced slope is the result of higher concentrations (and emissions) in 1997 and 1998. The figure also shows a reasonable relationship between the sets of annual emission data and the composite  $\text{SO}_2$  concentrations. Quarterly averages have declined significantly over the 10 years. Declines are more pronounced in the two colder quarters when  $\text{SO}_2$  emissions are higher and there is little photochemical conversion of  $\text{SO}_2$  to  $\text{SO}_4^{2-}$ .

Figure 2-9 presents trends in the 34-station composite, annual  $\text{SO}_2$  levels through a box diagram. The inter-site variability among the 34 sites is shown graphically by the 90th percentile, median, and 10th percentile values for the annual averages. The box plot shows results similar to the regression analysis. Years with lower average  $\text{SO}_2$  concentrations also show lower inter-site variability.

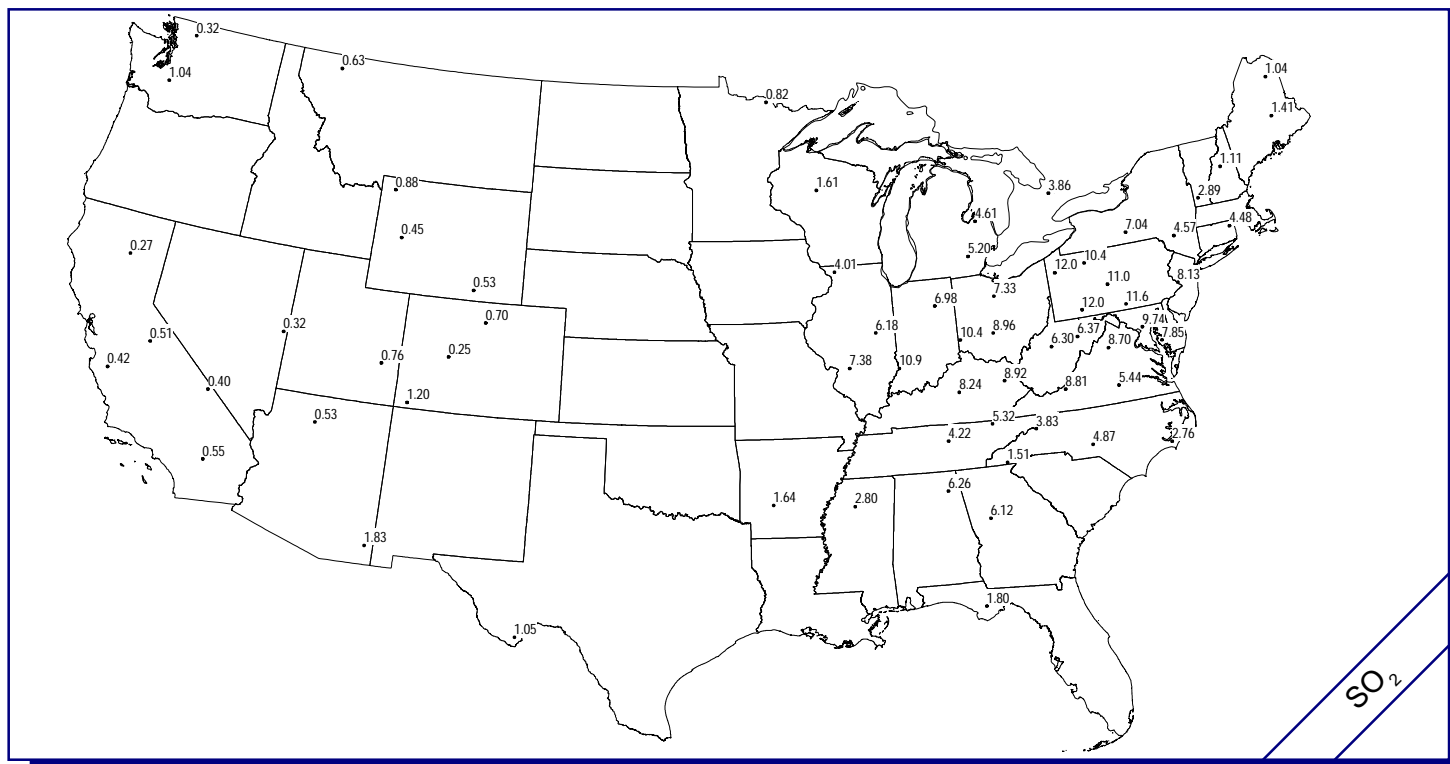

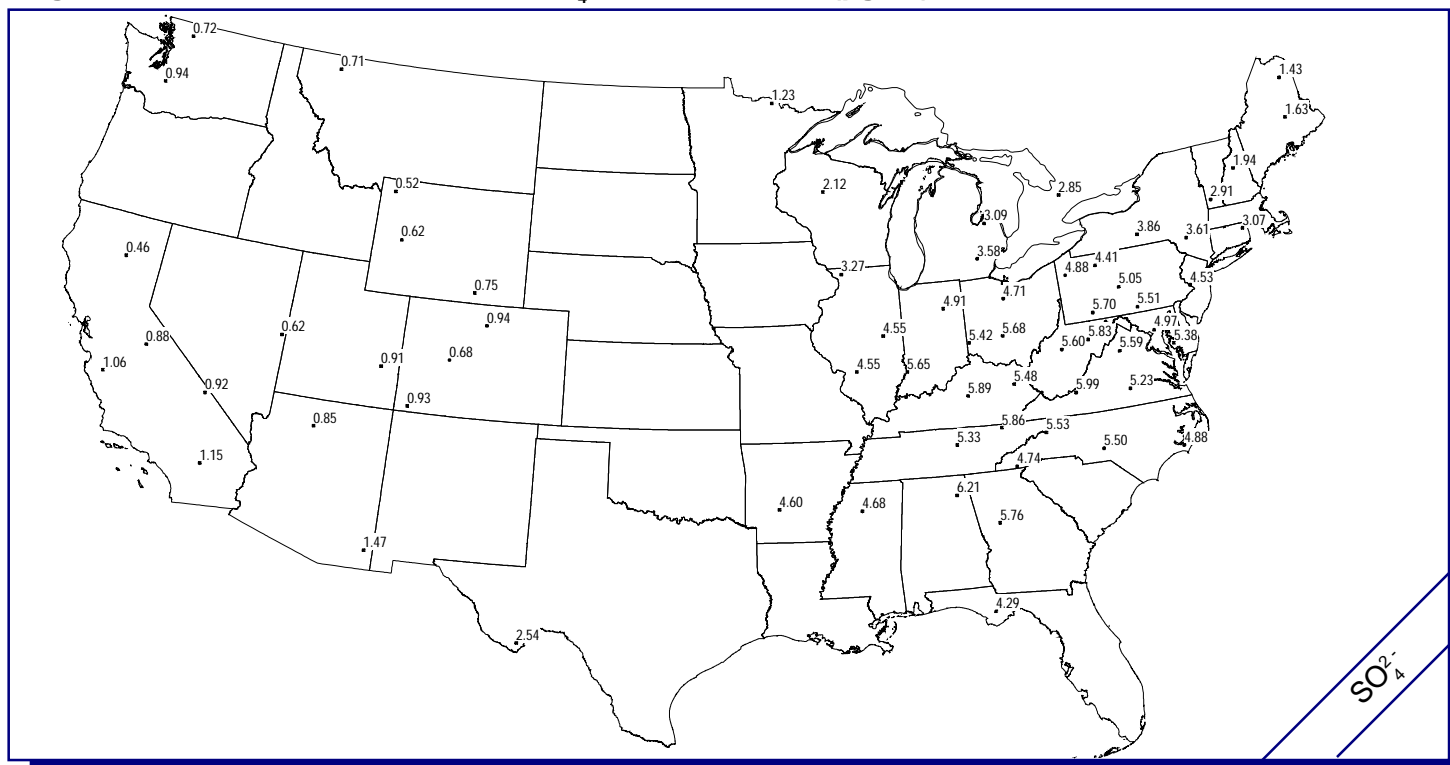

Trends in annual and quarterly  $\text{SO}_4^{2-}$  concentrations are shown in Figure 2-10. Annual  $\text{SO}_2$  emissions are also plotted. According to the linear model, annual  $\text{SO}_4^{2-}$  has declined by about 16% over the 10 years. Third quarter levels show the largest decrease. Concentrations peak in the third quarter because of the enhanced photochemical production of  $\text{SO}_4^{2-}$  from  $\text{SO}_2$ . The 1998 third quarter average is higher than those recorded in the previous few years. A box plot of annual  $\text{SO}_4^{2-}$  levels is given in Figure 2-11.

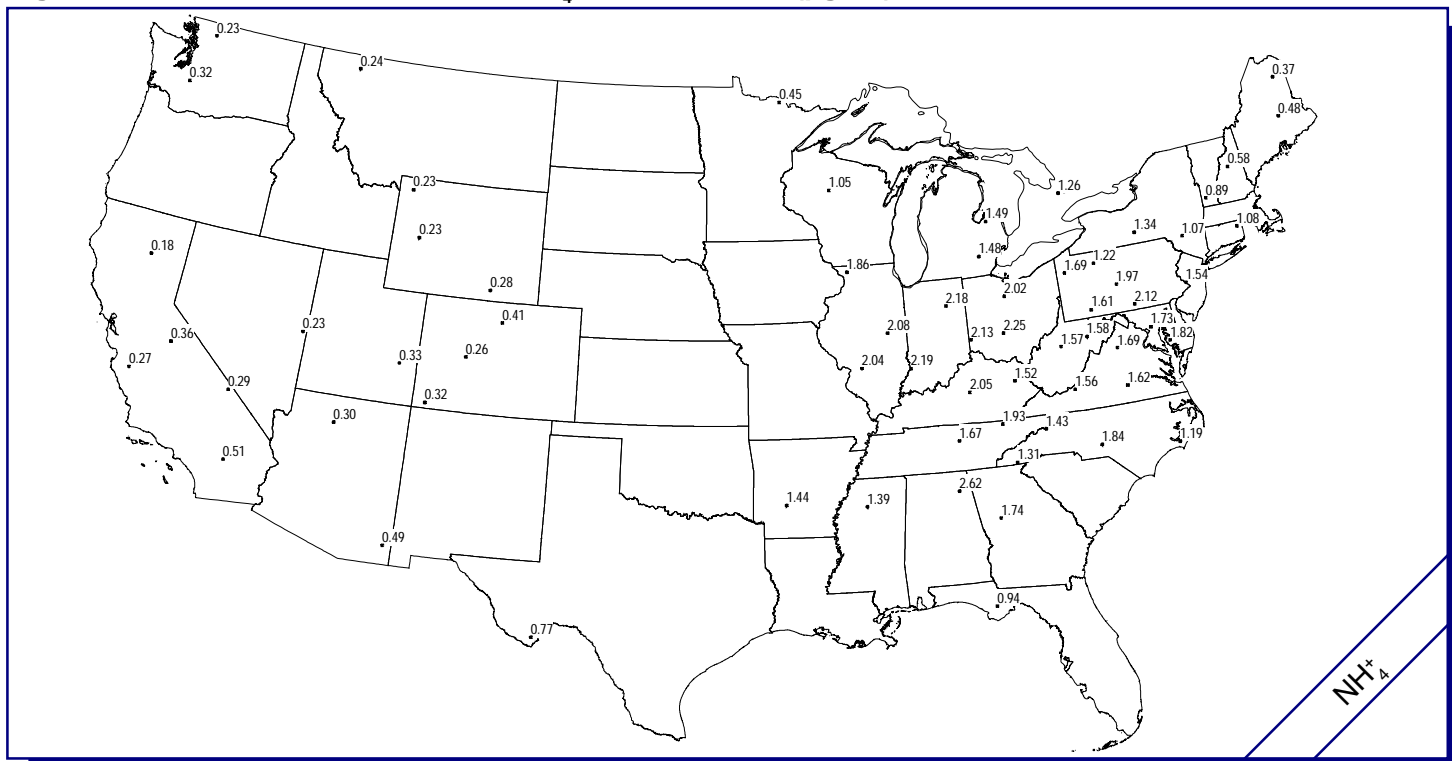

Linear regressions were also performed on annual and quarterly average  $\text{HNO}_3$  concentrations collected from 1989 through 1998. The  $\text{HNO}_3$  results for the 34-site composite averages are shown in Figure 2-12. Annual  $\text{NO}_x$  emissions are also shown. The results show a slight reduction over the 10-year period. A box plot for  $\text{HNO}_3$  is given in Figure 2-13.

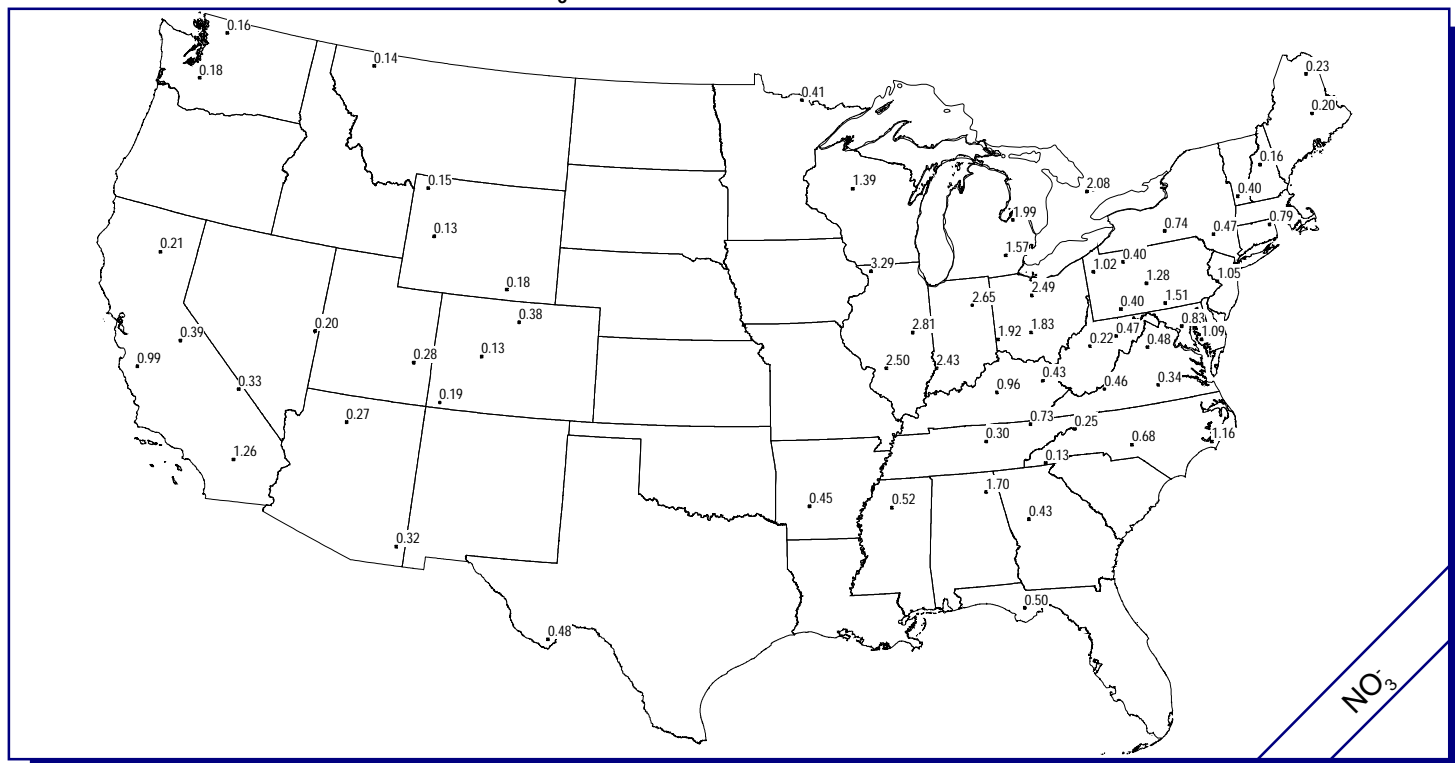

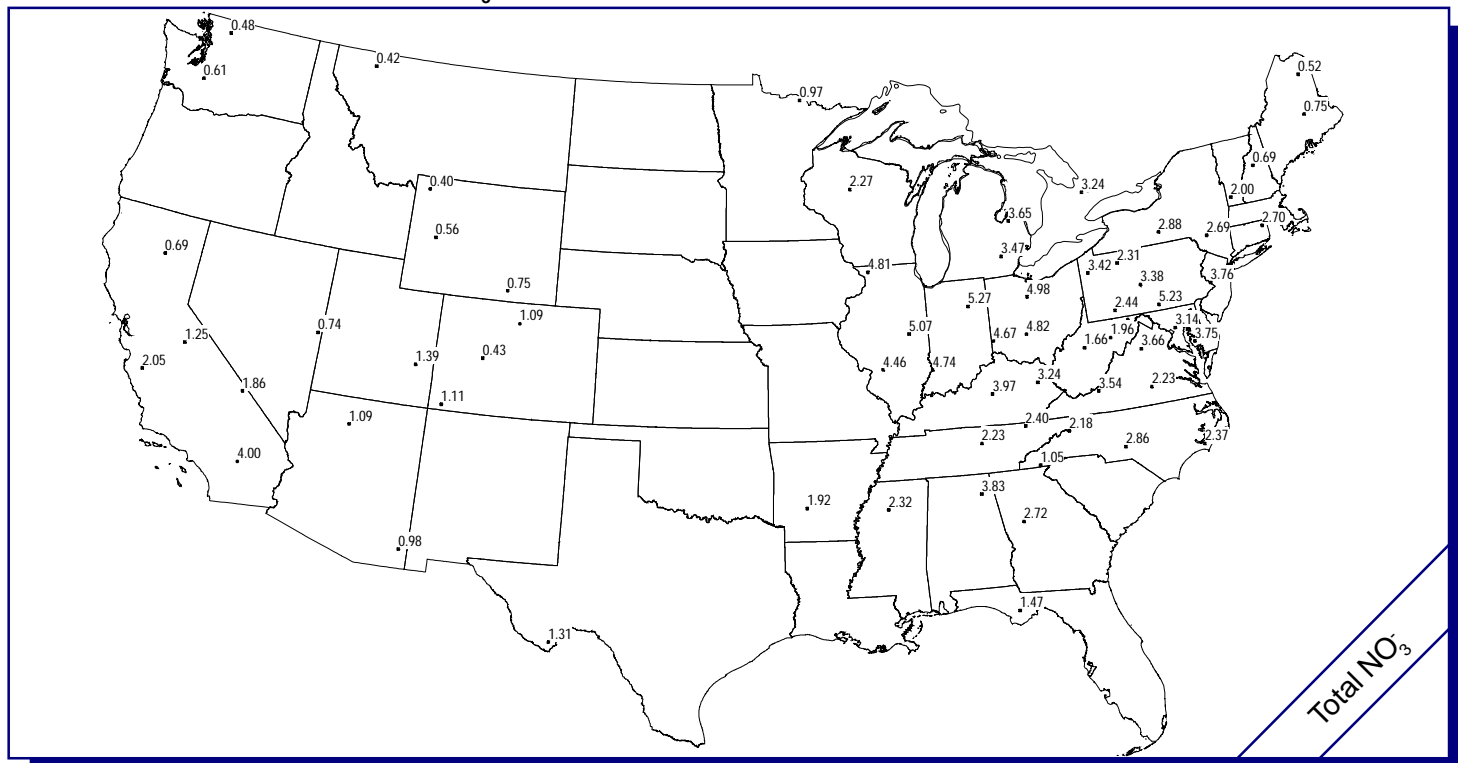

Linear regressions for annual and quarterly average  $\text{NH}_4^+$  concentrations for the 34-site composite database are shown in Figure 2-14. The linear model shows a slight reduction in the 34-station average values over the 10-year period. A box plot for annual average  $\text{NH}_4^+$  concentrations is shown in Figure 2-15.

Trends in annual and quarterly particulate  $\text{NO}_3^-$  concentrations are shown in Figure 2-16. Annual  $\text{NO}_x$  emissions are also plotted. The linear regressions show a slight reduction in concentrations over the 10-year period. A box plot is shown in Figure 2-17.

Trends in annual and quarterly total nitrate concentrations from the 34-station database are shown in Figure 2-18.  $\text{NO}_x$  emissions are also plotted. No trends are evident from the regression plots. A box plot of annual total nitrate concentrations is given in Figure 2-19.
